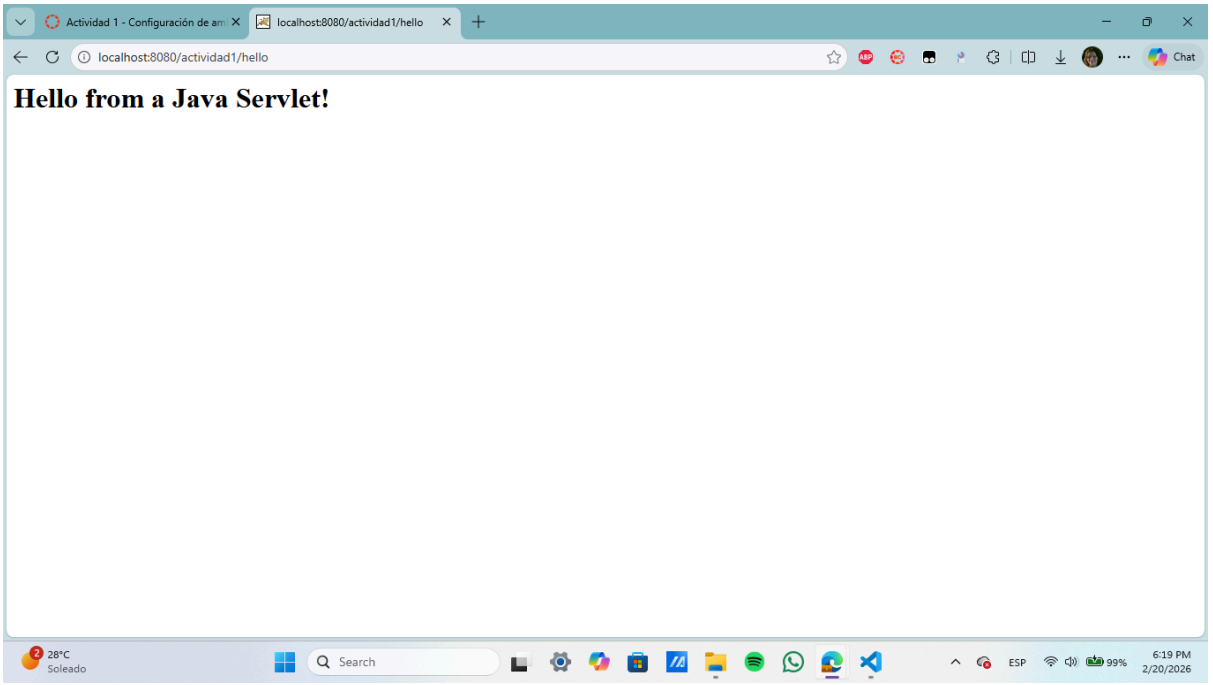
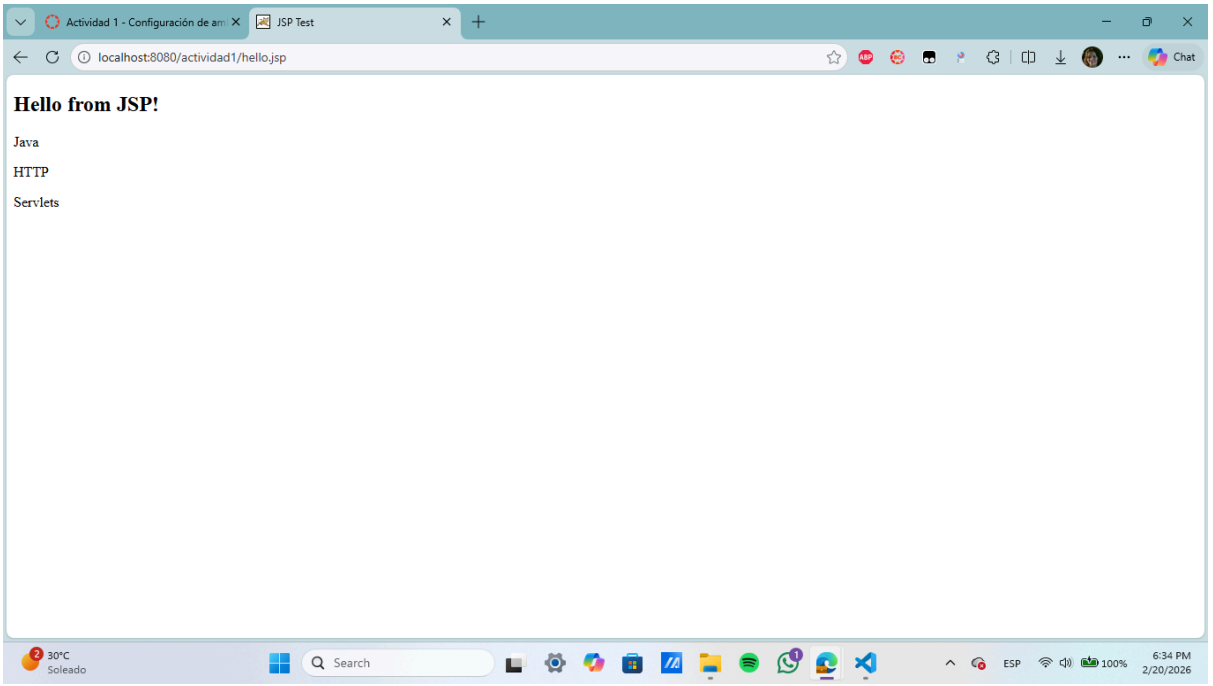
Part 2 Evidence

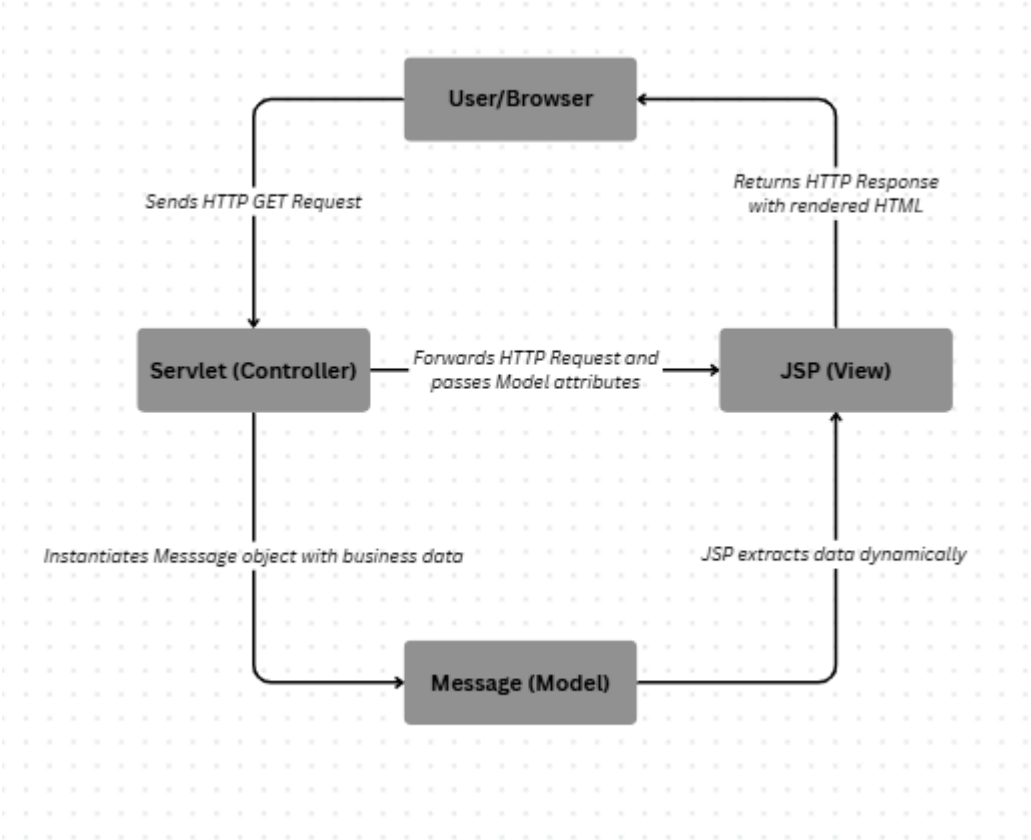


Part 3 Evidence



Part 4: Modern Web Application Architecture

1. **Diagram**



2. **Identify and organize responsibilities**

- *Controller (HelloServlet.java)*:

  It gets the HTTP request from the browser, decides which action to make, creating the data (Model) and sends the user to the correct page.

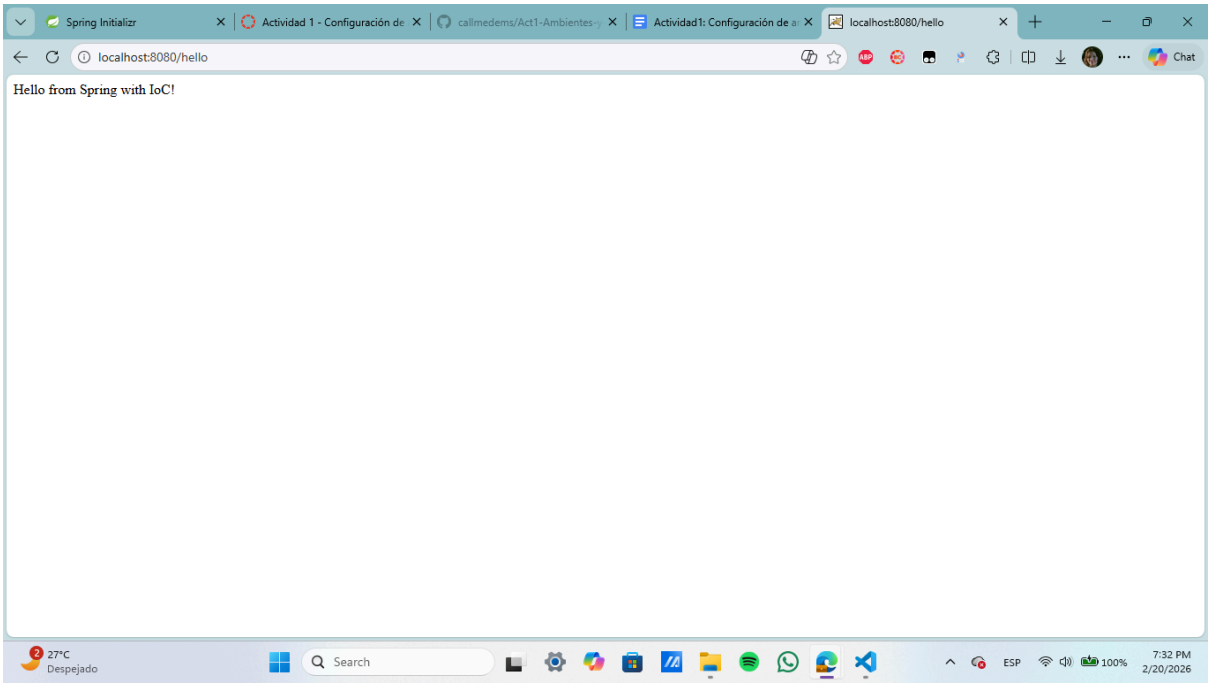
- *Model (Message.java)*:

  Represents business logic, and it is the raw data.

- *View(hello.jsp)*:

  It is the display, and it takes the data handed by the Controller, turning it into HTML for the user to see.

Part 5 Evidence



Evidence Paragraph:

As evidence of the completed exercise, I am submitting screenshots and a link to my running Java web server. I configured my environment from scratch using Visual Studio Code, installed the JDK, enabled the required extensions, and deployed a web application implementing a Servlet with its full lifecycle (init, service, and destroy), following the HTTP and Servlet concepts described in the provided material. In addition, I created a JSP with JSTL to generate dynamic content and analyzed how these components map to modern Java web architecture. Finally, I built a small Spring Boot service to apply the Inversion of Control (IoC) pattern and understand how dependencies are managed automatically by the framework.
